

COMAL 80
SYNTAX DIAGRAMS.

line:

statement:

Note:

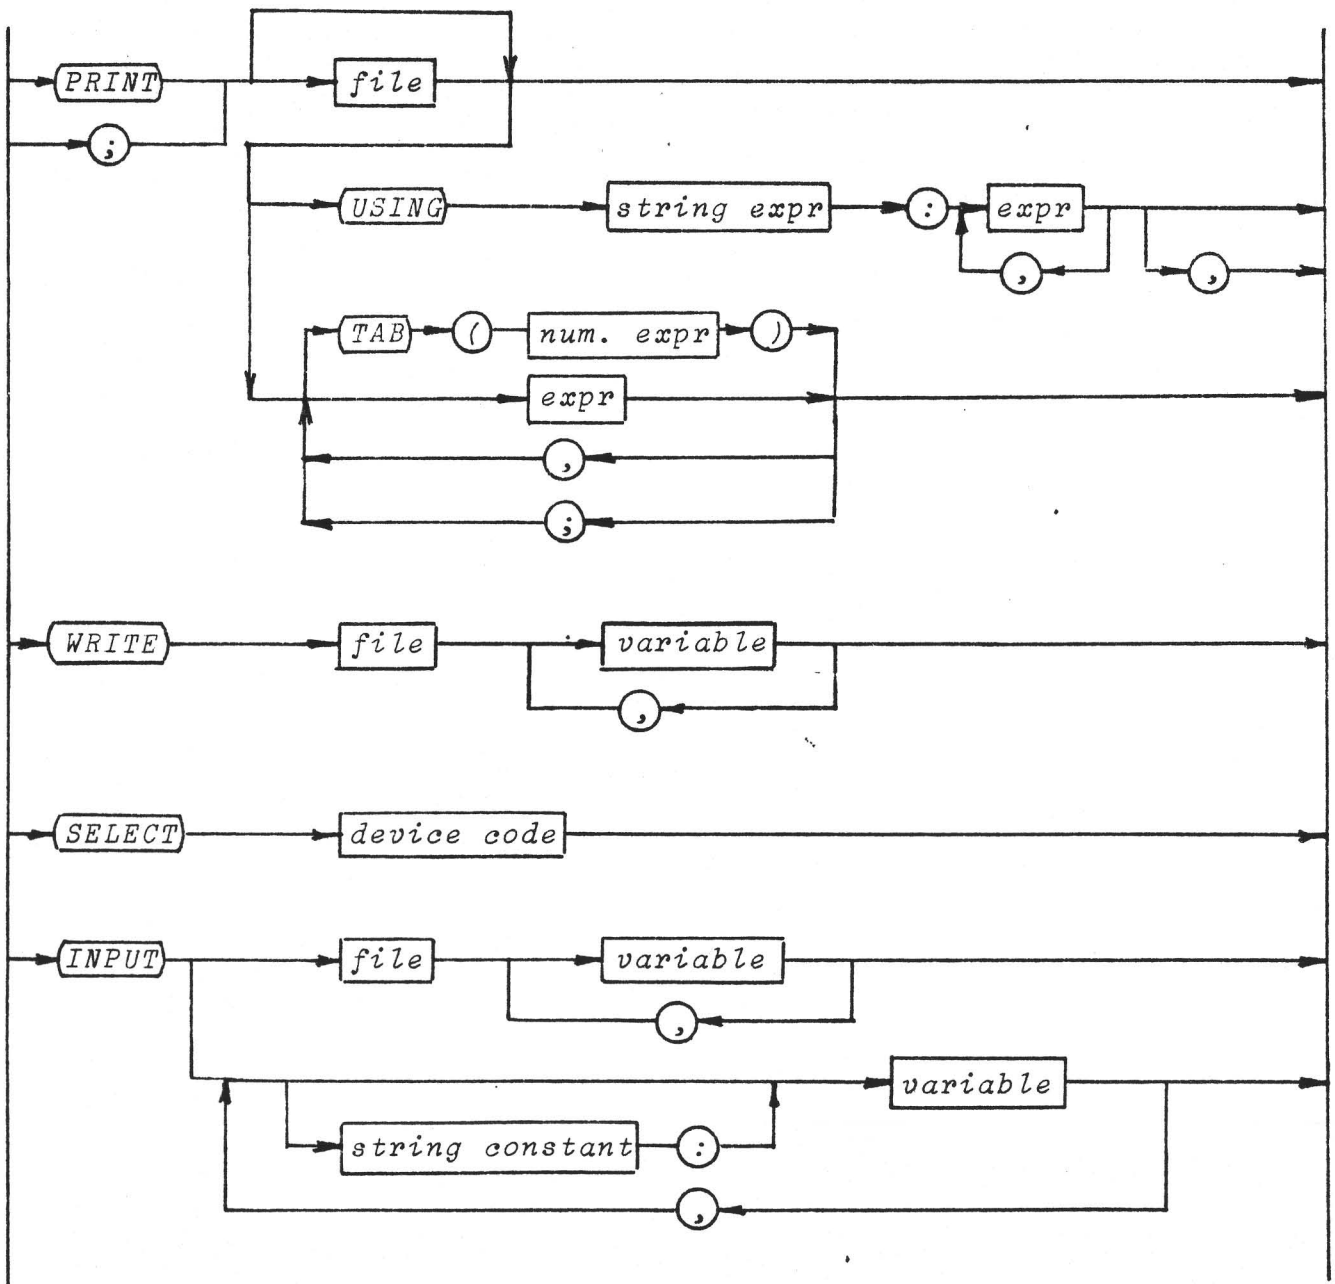

:+ may be used with strings, whereas :- may not.

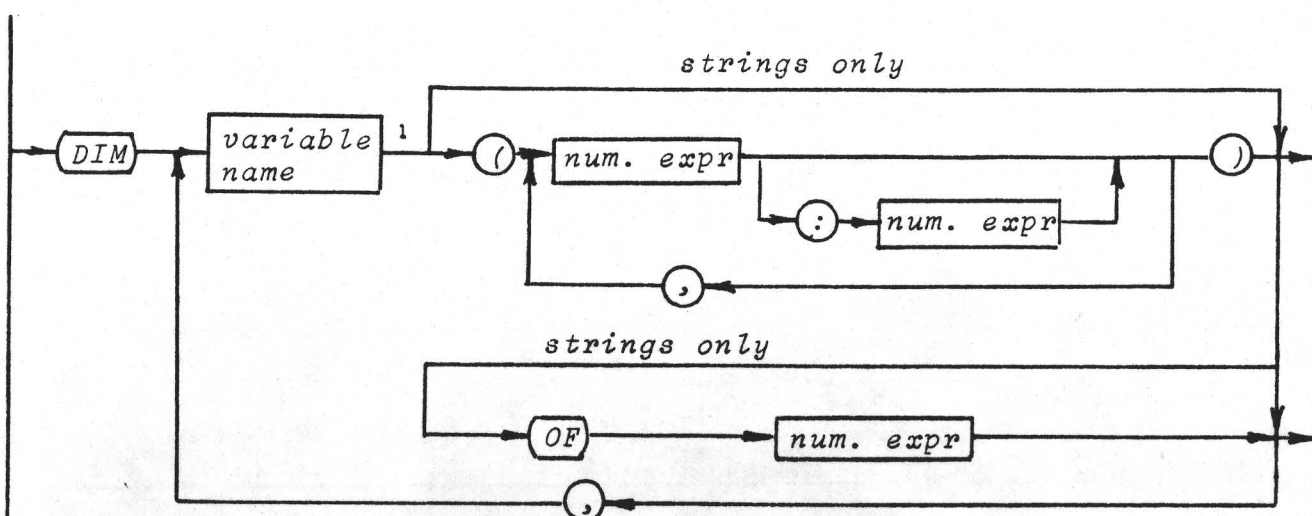

(note cont'd)

Variable and expression in an assignment must be of the same type. The only exception to that rule is:

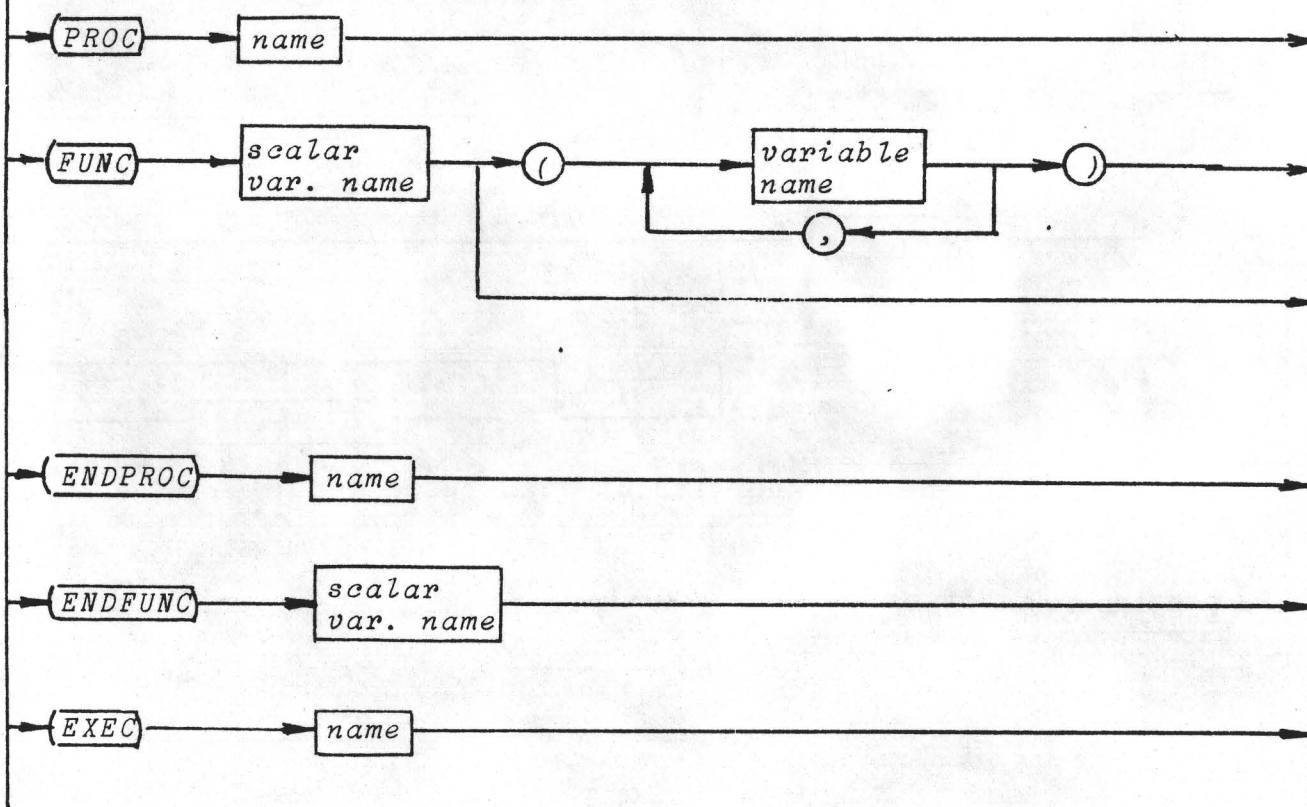

real variable := integer expression

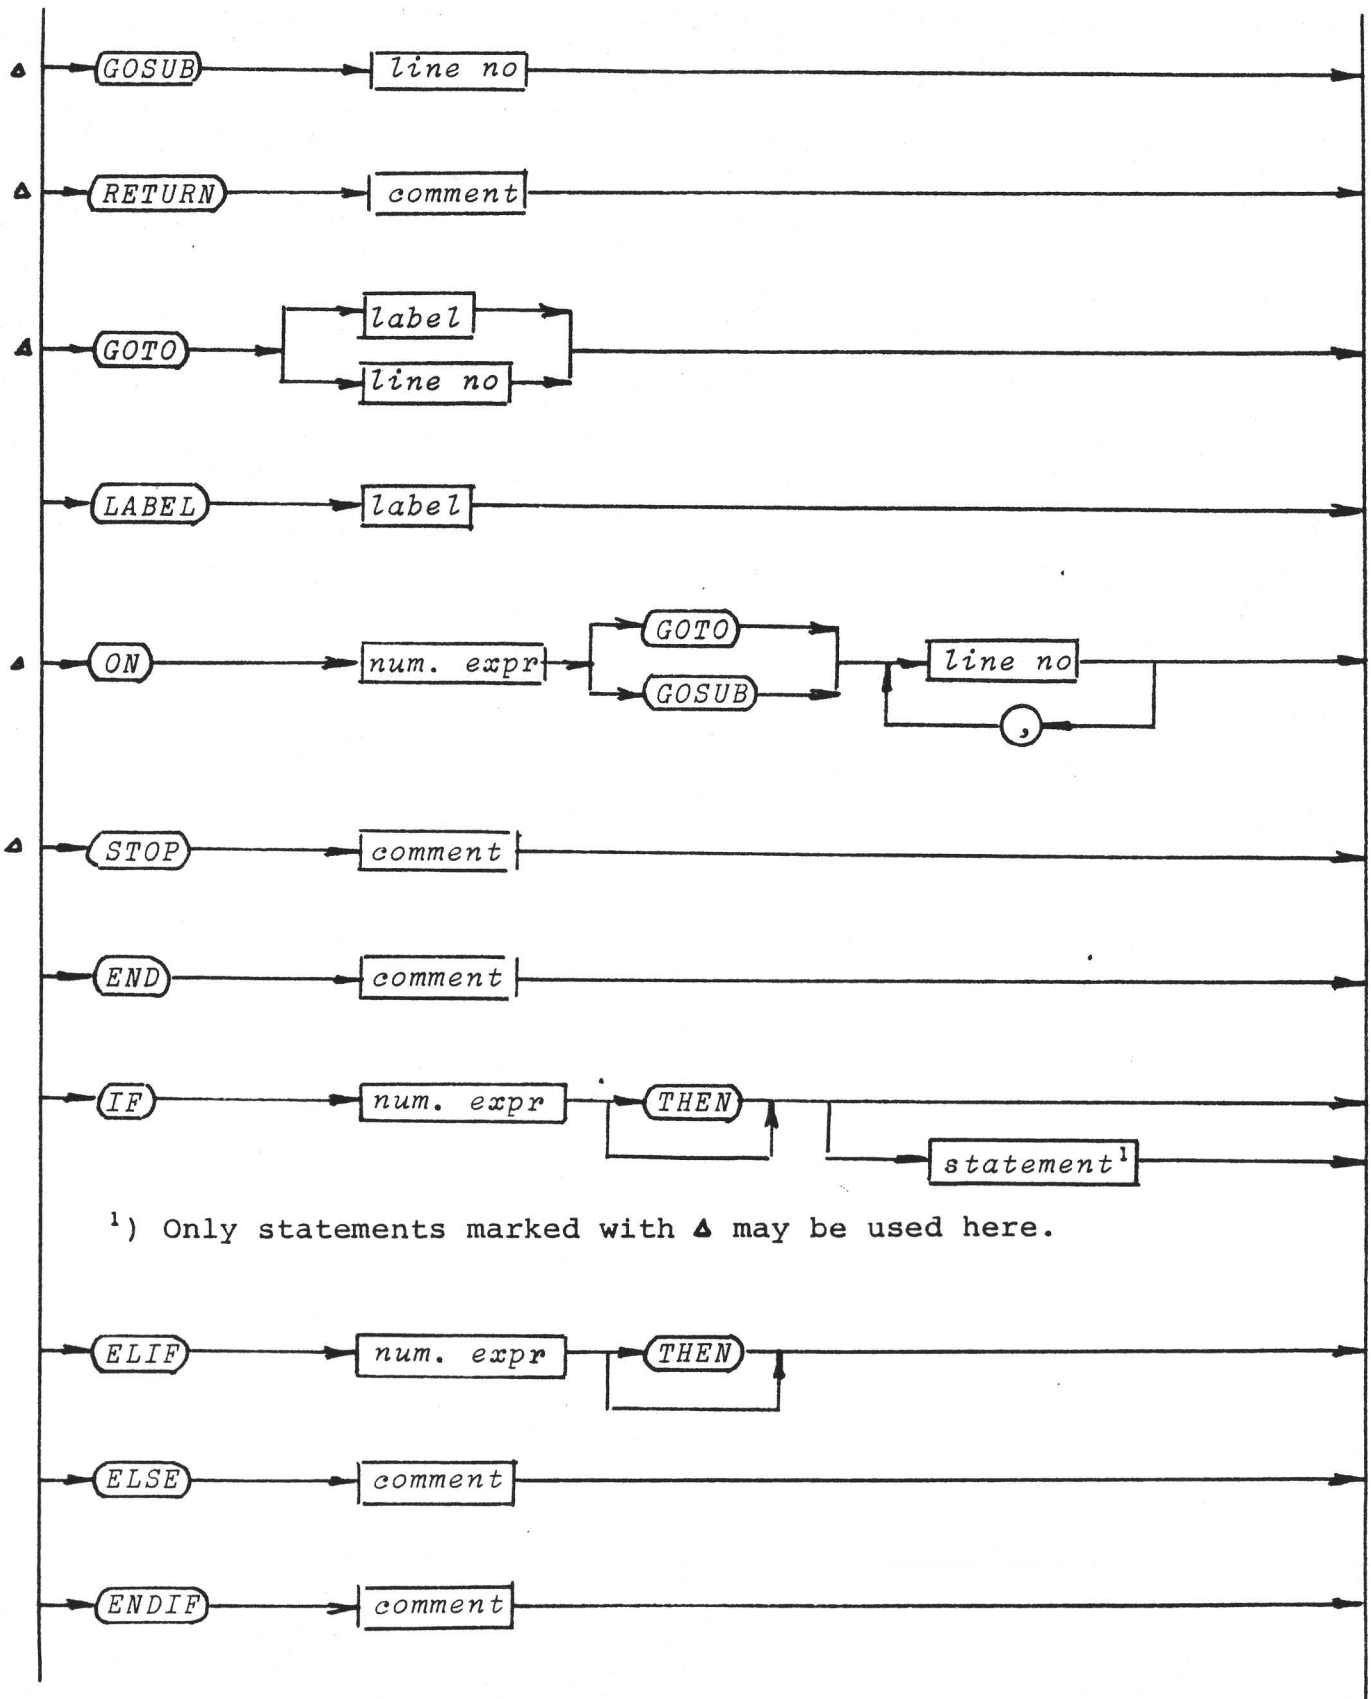

Variables must not be of type 'file' except where explicitly mentioned.

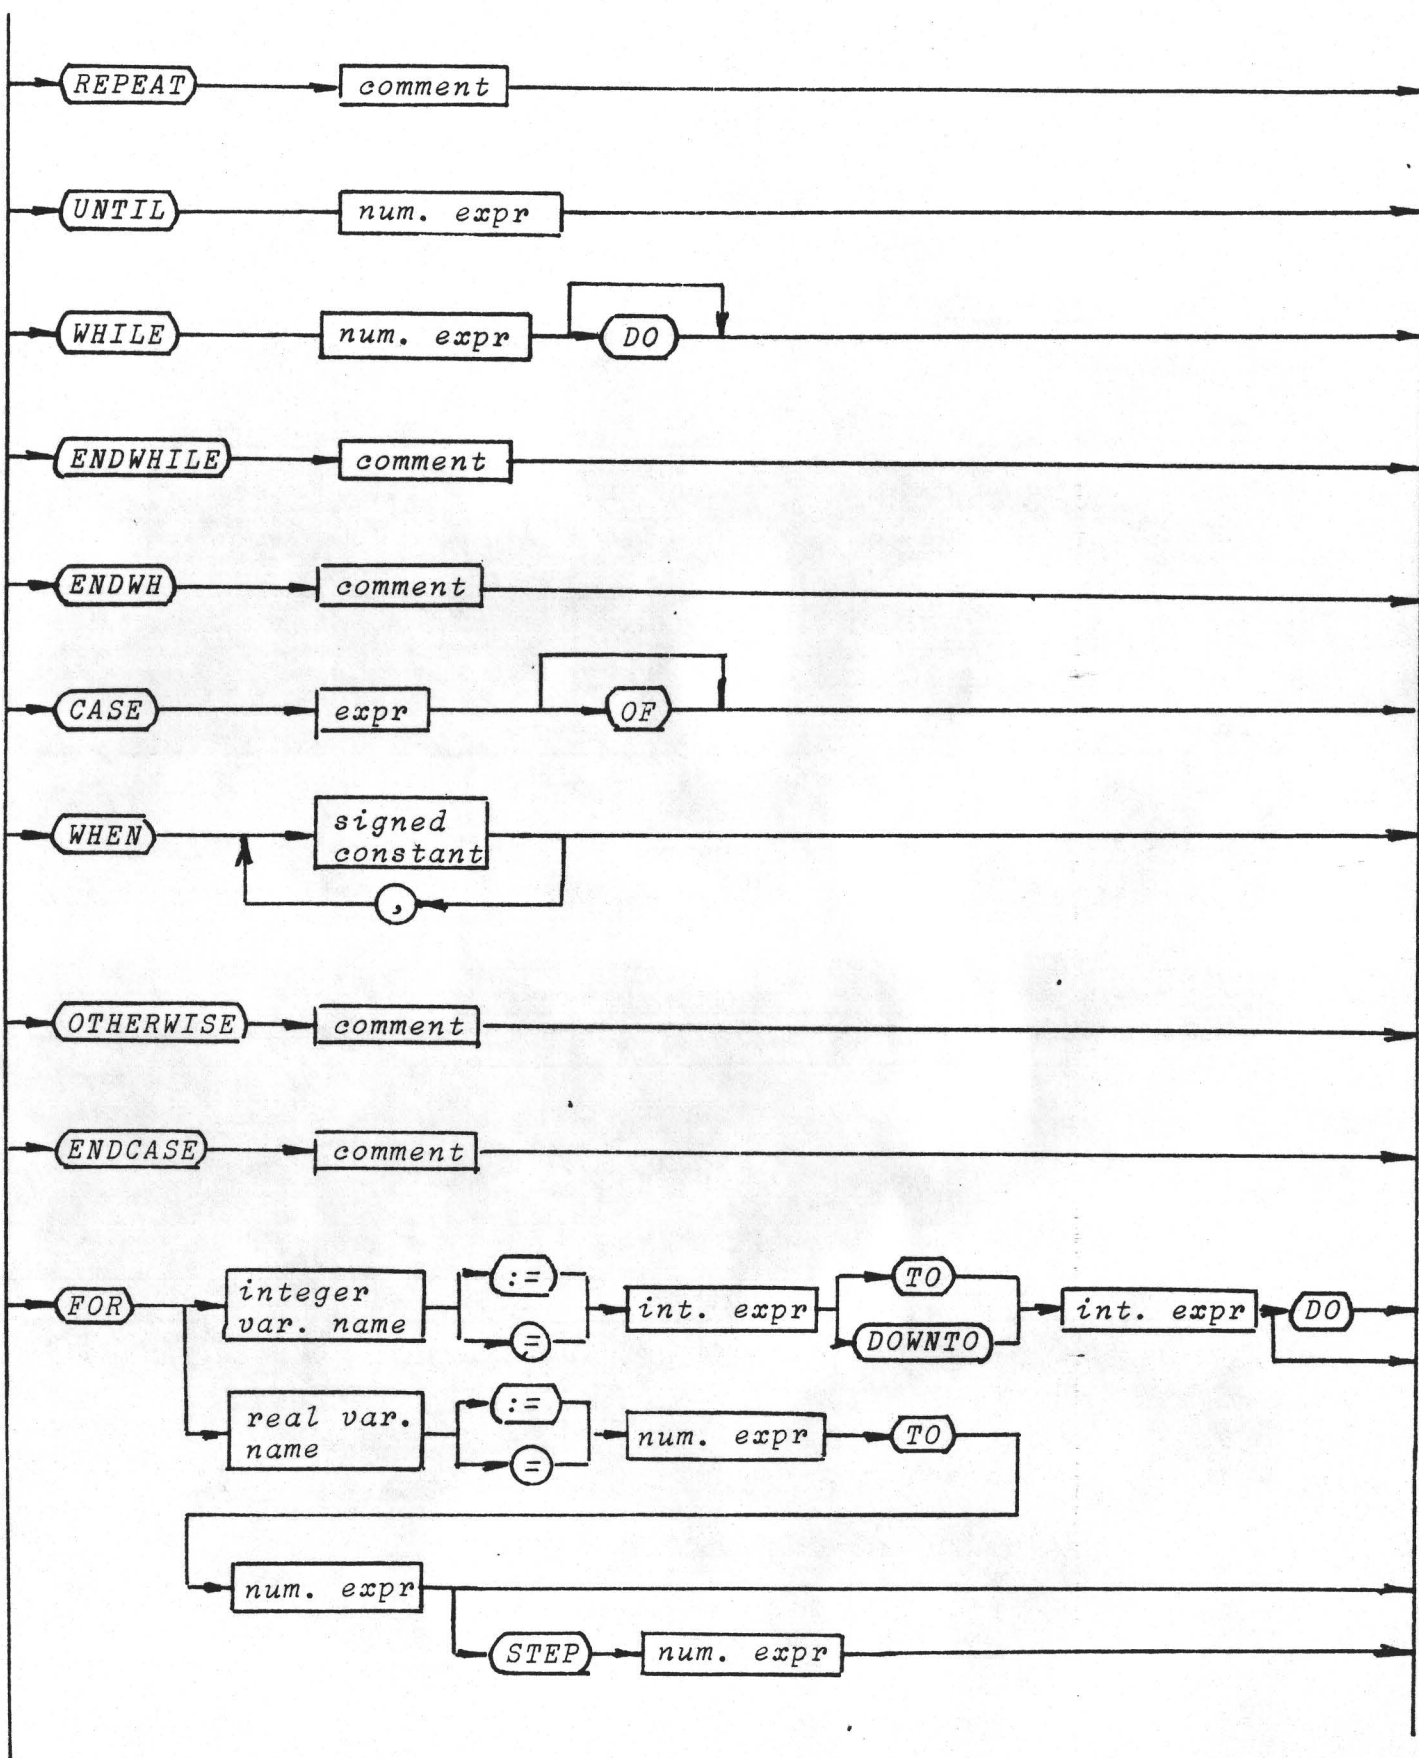

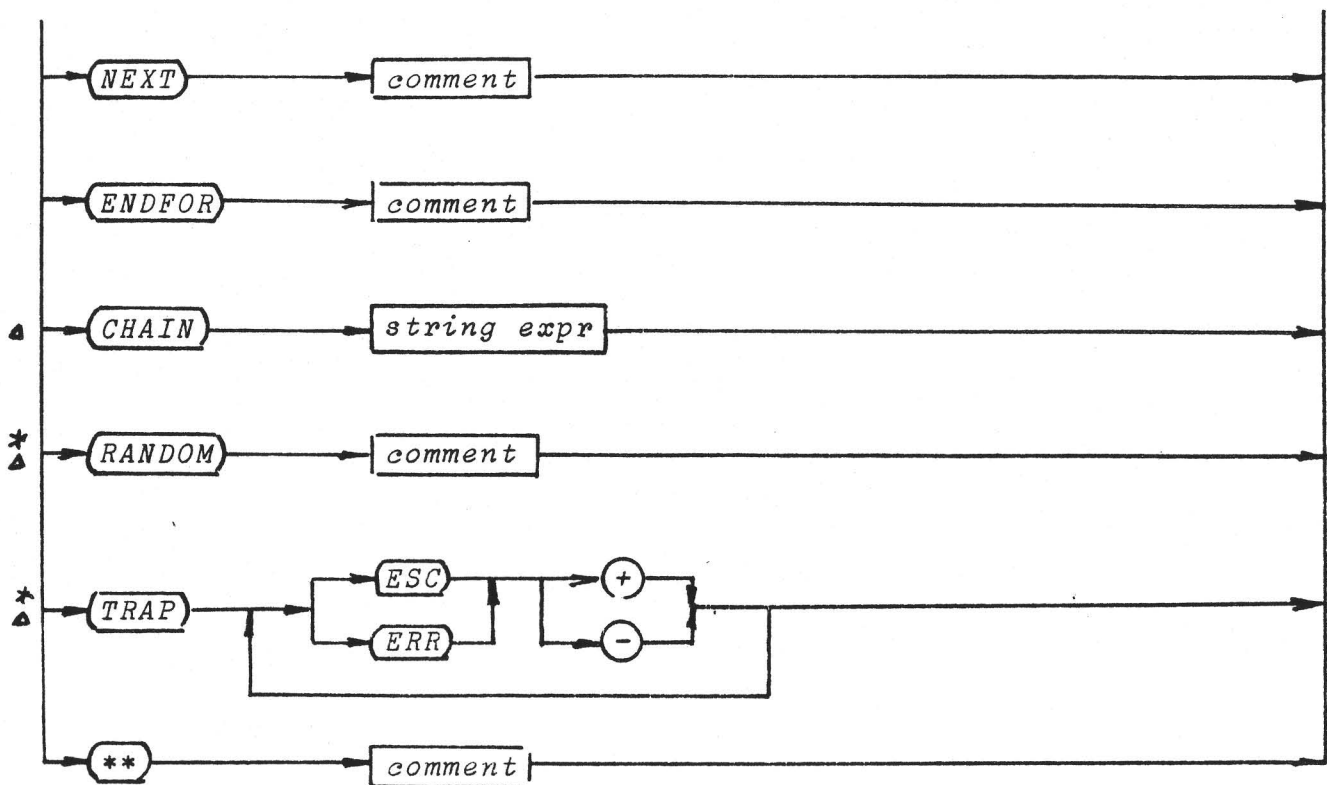

¹) File variable name allowed.

line no:

integer constant (1 - 9999)

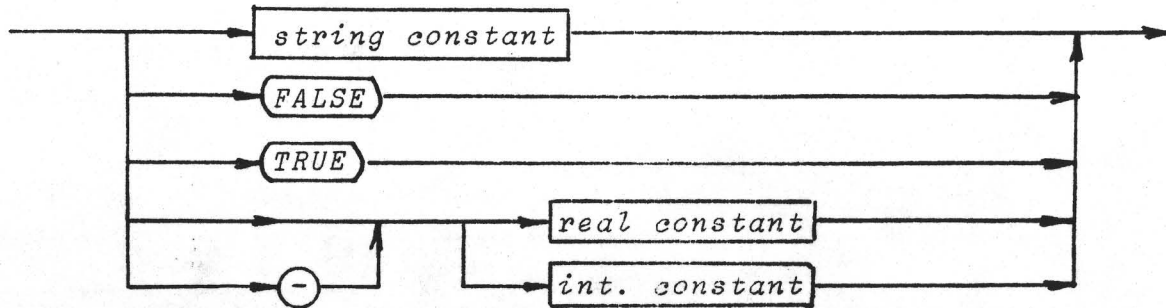

file:

file variable, num. expr, :

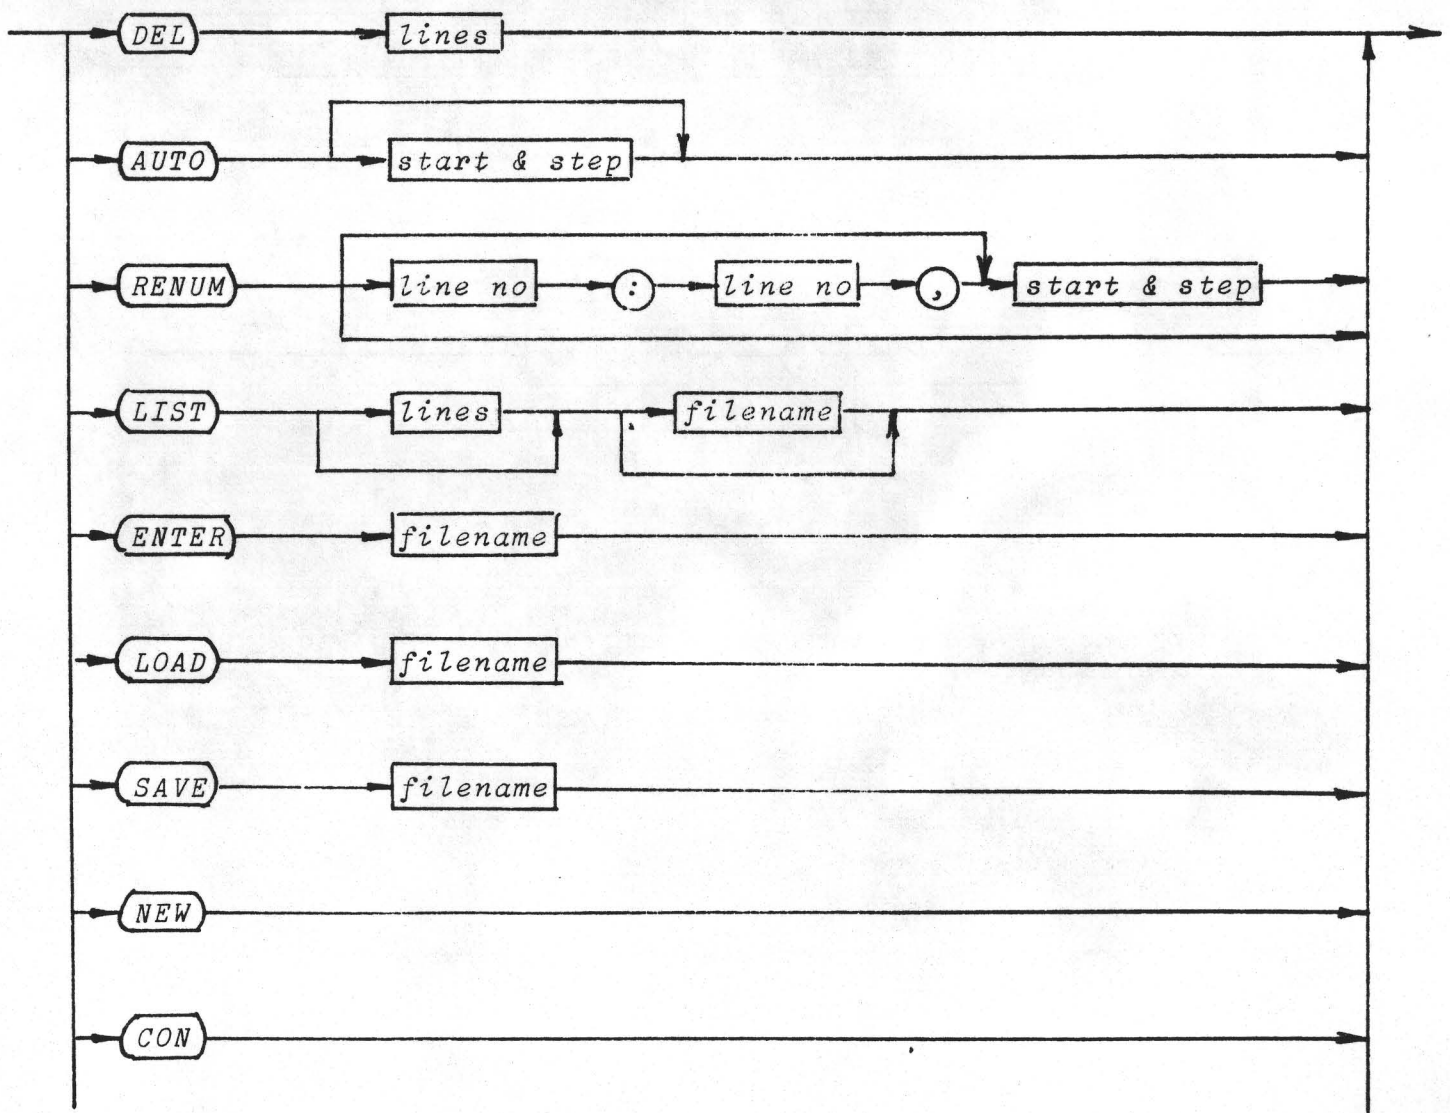

label:

COMMENTS TO THE SYNTAX DIAGRAMS

INTRODUCTION

COMAL 80 includes COMAL 75 and a version of BASIC. If two COMAL 80 versions differ, it will always be on the BASIC part, since the COMAL extensions are well defined. Only structured BASIC which includes these extensions may be called COMAL. The COMAL 80 extensions of COMAL 75 have been carefully designed to meet the needs of users as observed through four years work with COMAL 75.

The following exposition will deal mainly with the statements that define COMAL. BASIC statements will be mentioned only where they have been subject to changes due to the definition of COMAL. Since the COMAL statements have been introduced to facilitate structured programming, the syntax diagrams can only unveil very little of the true power of these statements that has to be seen in global contexts. Great care will therefore be taken to display the structures controlled by the most important COMAL statements.

LET

For educational purposes assignment in COMAL may be denoted by the symbol

`:=`

For reasons of compatibility it is, however, allowed to use an ordinary sign of equality when typing in the program. The interpreter will automatically convert this sign to `:=`.

The symbols

`:+` and `:-`

may be used in assignments where the same variable appears on both sides. Thus

`NUMBER:+1`

is equivalent to

`NUMBER:=NUMBER+1`

A LET statement will take as many assignments as the line width permits, each individual assignment being separated from the next one by means of the semicolon (;).

MAT

May be used to assign values to all components in an array. Thus the statement

```
MAT ACCOUNT:=0; FOUND#:=FALSE
```

where ACCOUNT is an array of reals and FOUND# an array of integers, will assign a value of 0 to each component of ACCOUNT and a value of FALSE (=0) to each component of FOUND#.

SELECT

May be used as command or statement. Device code could be for example: LPT (lineprinter), TTY (teletype), or PTP (punch). The statement

```
SELECT LPT
```

causes the output from all following PRINT statements to be sent to the lineprinter. The statement

```
SELECT TTY
```

resets the function back to normal teletype output. Output from string constants in INPUT statements is not affected by the SELECT.

EXEC, PROC, ENDPROC

If part of a program is initiated with the statement

```
PROC name
```

where *name* is a string formatted as a variable name, and is terminated with the statement

```
ENDPROC name
```

this program may be called as a subroutine by another program using the statement

```
EXEC name
```

When the subroutine has been executed, control is passed to the statement following the EXEC statement that called the subroutine.

The program text between the PROC and ENDPROC statements is indented in the program listing.

FUNC, ENDFUNC

If a subprogram is initiated with the FUNC statement and terminated with the ENDFUNC statement, it may be used by another program as a predefined function. All variables introduced in the lines between FUNC and ENDFUNC are local and global variables cannot be accessed from these lines. Parameters may be simple variables of any type, and they are all called by value.

The output from the function is returned through the functions name (i.e. the scalar variable name immediately following the FUNC keyword). Thus an assignment like this:

function name:=expression of correct type

must appear somewhere in the body of the function.

Example.

```
FUNC GCD#(X#,Y#)
...
...
GCD#:=A#
ENDFUNC GCD#
```

This function is used in the statement:

```
IF GCD#(A#,B#)=1 THEN PRINT "A AND B ARE REL. PRIMES."
□□□
```

GOTO, LABEL

Addresses for GOTO may be given by labels in COMAL. Also the RESTORE statement may use a label. Thus the statement:

```
RESTORE NAMES'OF'PERSONS
```

will set the data pointer to the first element in the queue

defined by the DATA statements following the statement:

LABEL NAMES 'OF' PERSONS

The first of the DATA statements referred to must follow immediately after the LABEL statement.

IF, ELIF, ELSE, ENDIF

Note: A numerical expression is in proper context considered false, if it has a value of 0, and true in all other cases.

The four statements provide the following:

a. IF .. ENDIF

IF expr THEN

ENDIF

If the expression has a value equivalent to true, program section A is executed. If the expression evaluates to false, program section A is ignored.

The program text between IF and ENDIF is indented in the program listing (cf. FOR .. NEXT in most BASIC versions).

b. IF .. ELSE .. ENDIF

IF expr THEN

ELSE

ENDIF

If the expression evaluates to true, program section A is executed. If the expression has a value equivalent to false, program section B is executed.

The program text between the control statements is indented in the program listing.

c. IF .. ELIF .. ELIF ELSE .. ENDIF

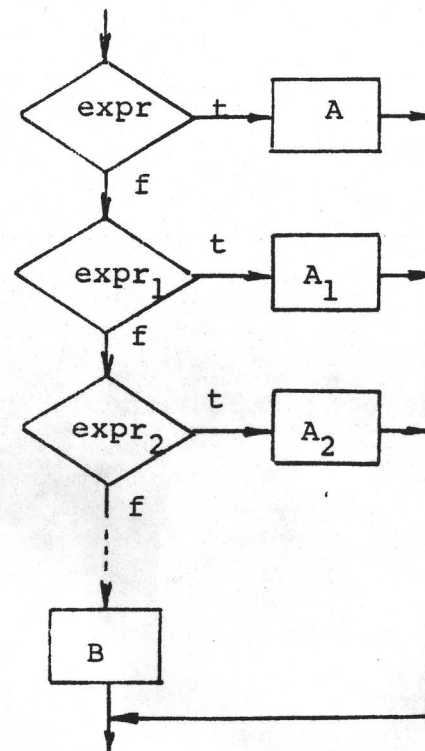

(diagram on next page).

The keyword ELIF is an abbreviation of ELSE IF. As the flowchart that accompanies the diagram will show, only one of the processes described in the structure is executed. Note that if more than one of the expressions may be evaluated to a value of true, only the first one will

trigger off a process.

```

IF expr THEN
    A
ELIF expr1 THEN
    A1
ELIF expr2 THEN
    A2
...
ELSE
    B
ENDIF
    
```

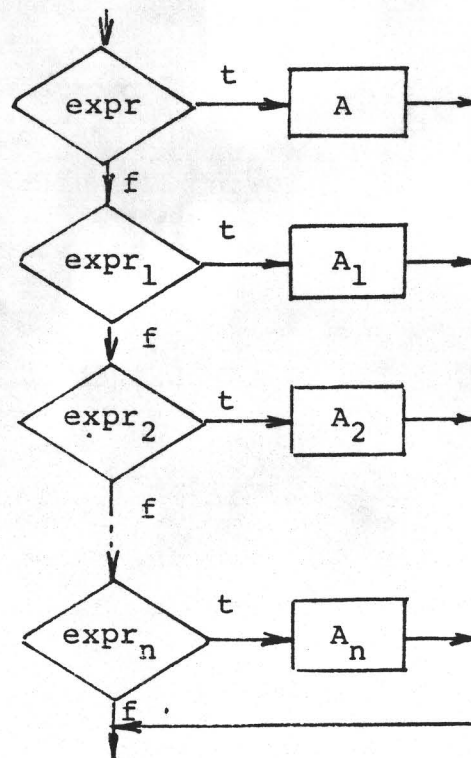

If the final alternative ELSE is left out, you get

d. IF .. ELIF .. ELIF ENDIF

```

IF expr THEN
    A
ELIF expr1 THEN
    A1
ELIF expr2 THEN
    A2
...
ELIF exprn THEN
    An
ENDIF
    
```

REPEAT, UNTIL

The REPEAT and UNTIL statements provide the following structure:

REPEAT

UNTIL expr

Program section A is executed repetitively until the expression following UNTIL has a value equivalent to true. When this happens, control passes to the statement following the UNTIL statement.

The program text between REPEAT and UNTIL is indented in the program listing.

WHILE, ENDWHILE, ENDWH

The WHILE and ENDWHILE (ENDWH) statements provide the following structure:

WHILE expr DO

ENDWHILE (ENDWH)

Program section A is executed repetitively while the expression following the WHILE keyword is evaluated to true. When the expression evaluates to false, control passes to the statement following ENDWHILE (ENDWH).

The program text between WHILE and ENDWHILE (ENDWH) statements is indented in the program listing.

CASE, WHEN, OTHERWISE, ENDCASE

(diagram on next page)

When the expression following CASE has been evaluated, the list following the first WHEN is examined. If one of the constants in this list is equal to the value of the expression, program section A₁ is executed, and control is then passed to the statement following ENDCASE. If no such item is found, the list following the second WHEN is examined. If the value of the expression is found, A₂ is executed,

and control is then passed to the statement following ENDCASE. If the value still has not been found, the interpreter starts on the third list etc.

A default case (program section B) may be inserted and is executed if the value of the expression is not found in any of the lists following the WHEN keywords. The default case is indicated by the keyword OTHERWISE.

CASE expr OF

WHEN list₁

A₁

WHEN list₂

A₂

...

WHEN list_n

A_n

OTHERWISE

B

ENDCASE

The OTHERWISE case may be left out, but the interpreter will then stop the execution of the program with an error message if no constant corresponding to the value of the expression has been found in the WHEN lists.

Note that at most one of the cases is executed. If it so happens that the value of the expression may be found in more than one of the lists, only the first of these lists will trigger off its process.

The program texts A₁, A₂, ..., A_n, B are indented in the program listing.

FOR, ENDFOR

The FOR .. NEXT loop structure from BASIC has been extended. As seen from the syntax diagram, you may use a statement like this:

FOR I#:=10 DOWNT0 1 DO

The "stepvalue" is then automatically set to -1. FOR loops with integers are very fast.

ENDFOR may be used for NEXT. The countervariable may or may not occur after NEXT and ENDFOR. The interpreter will in any case look upon it as a comment.

TRAP, ESC, ERR

Two dedicated flags ESC and ERR may be set or reset using the TRAP statement. A + will set the flag, and a - will reset it. When the interpreter starts, the two flags are set, and that means that the ESC key will cause a break whenever struck, and that errors will cause an error message and a program stop. If, however, one of the flags is reset, the interpreter will not react to the said conditions unless this has been defined explicitly in the program. This may be done by statements like:

```
IF ESC THEN EXEC TEST02
```

or

```
WHILE NOT ERR DO
```

COMMENTS

Since comments are allowed after any statement, directly or by using **, the REM statement is left out. It may of course be introduced in the BASIC part for compatibility if wished. This has nothing to do with the definition of COMAL.

TRUE, FALSE

To improve the readability of the programs two constants TRUE and FALSE are predefined. TRUE is equivalent to 1, and FALSE is equivalent to 0.

AND, OR, NOT

In COMAL you have full Boolean algebra at your disposal. As mentioned before a numerical expression is in proper context considered false, if it has a value of 0, and true in all other cases. A Boolean expression like

```
NUMBER>MAX'NUMBER OR NOMORE
```

will output a value of 1, if it is true, and a value of 0, if it is false. A statement like this:

```
FOUND:=(NAME$=STUDENT'NAME$(I))
```

will assign a value of 1 to FOUND, if the condition to the right of the := is met, and a value of 0, if not. Thereafter FOUND may be used as if it were a Boolean variable. The "pseudo Boolean" values 0 and 1 are represented as integers (2 bytes) so it may speed up the program, if integer variables are used for "Boolean purposes".

IN

The expression:

```
NAME$ IN TEXT$
```

will output a value of 1, if NAME\$ is found as a substring in TEXT\$, and a value of 0, if it is not found.

Example

```
IF CH$ IN VOWELS$ THEN VOW#:=TRUE
```

```
□□□
```

NAMES

Variable names may contain as many characters as you wish. The first character must be a letter, the following may be letters, digits, or the sign '.

Example.

```
NUMBER'OF'STUDENS, MAXNUMBER, NUMBER, NAME$, NAME'OF'STD$
```

```
□□□
```

APPENDIX 01

Survey of the data types which the different operators may work on, and the resulting type.

left right operand		operator					
		↑	/	*	DIV MOD	+ -	IN AND OR
str	str					str*	int
int	int	real	real	int	int	int	int
int	real	real	real	real	real	real	int
real	int	real	real	real	real	real	int
real	real	real	real	real	real	real	int

The relational operators: < <= > >= = <>
may work on any pair of strings and any pair of numerical expressions. The output will be an integer 1 or an integer 0. ("pseudo true" and "pseudo false").

The blank positions in the table mean that the corresponding operator may not be used with the set of operands.

*) Not -

Standard functions.

ATN, COS, SIN, TAN, LOG, EXP, SQR, FRAC, RVAL: real

CHR, STR: string

SGN, LEN, ORD, IVAL, INT, POS: int

EOD, ESC, ERR, EOF: int

ABS: same type as argument

RND: { without arguments: real
with arguments: int (arg. gives limits).

SPC: outputs a string which consists of as many blanks as the argument gives.

APPENDIX02

XCOMAL 80 SYNTAX DIAGRAMS

actual parameter list:

VAR

The VAR statement may be used in stead of the DIM statement. Variables, declared by means of the VAR statement within the body of a procedure, are local to that procedure. Therefore simple variables may occur in the list following the keyword VAR.

Example

If the statement

```
VAR I,J,NUMBER,NAME$(40) OF 30
```

appears in the body of a procedure, the variables I and J, and the array NAME\$ will be local to that procedure.

□□□

PARAMETERS

Parameters for procedures may be called by value or by reference. If a parameter name begins with the character †, it is called by reference and otherwise it is called by value. If an array is referred to by a parameter, its dimension must be indicated by means of parentheses and commas. Thus

```
†NUM(,)
```

indicates a parameter that refers to a two dimensional array of numbers and is called by reference.

Example

```
PROC SORT(†ACCOUNT(),MAX)
```

The first parameter must be called by reference and the second one must be called by value. The first one will refer to a one dimensional array of numbers, the second one will be assigned the value of a number.

□□□

Procedures may be called recursively.
